Final – Version 001-1

The exam is worth 100 points. Each question (eight questions on eight pages) is of equal value.

1. Suppose a consumer gains utility from three goods (x, w and z) and faces the utility function $u(x, w, z) = x + 2w + z$. Assume w is fixed at 5 units. Draw the indifference curve for $u = 40$ (show one relevant consumption bundle on the indifference curve). What is the marginal rate of substitution of x for z? Suppose w increases to 10 units. On the same graph, draw the indifference curve for $u = 40$ (show one relevant consumption bundle on the indifference curve). What is the marginal rate of substitution of x for z now?

2. Suppose a consumer gains utility from two goods (x and y) and faces the utility function $u = \min(x, y)$. Draw a potential budget constraint and show where the consumer would maximize their utility. Now, suppose the price of x falls. Show the new utility maximizing point on the same graph. Explain what happens via income and substitution effects.

3. Consider the following production function: $q = L^{1/2}$, where L represents the amount of labor used by the firm. Suppose the firm is a price taker. Noting that the short-run marginal cost curve is the short-run supply curve for the firm, derive the short-run supply curve and plot it on a graph. Suppose there is an increase in wages (w), show the effect on the short-run supply curve.

4. Consider the following production function: $q = K^{1/2}/L^{1/2}$. Show whether this production function exhibits increasing, decreasing or constant returns to scale? What types of allocations of inputs (K & L) lead to maximal output (q)?

5. Suppose we are in the very short-run and the supply of a good is fixed at 10 units. Suppose the demand curve is $p = 20 - q$. Derive the equilibrium price and quantity. Calculate both the consumer and producer surplus in this situation. Use a graph.

6. Suppose there are two firms in a market. The short-run supply curve for firm 1 is $p = 5 + 2q$ and the short-run supply curve for firm 2 is also $p = 5 + 2q$. What is the market supply curve in the short-run? If the market demand curve is given by $p = 20 - q$, what are the market equilibrium price and quantity? Use a graph and label the relevant axes, curves, etc.

7. Consider two consumers (1 and 2) who can consume two different goods (A and B). Suppose the utility function for the first consumer is $u_1(A, B) = A + B$ and the utility function for the second consumer is $u_2(A, B) = 2A + 2B$. Draw an Edgeworth Box for this situation. Draw a single indifference curve for each consumer in the box. What does the contract curve look like for this setting?

8. Suppose the demand curve that a monopolist faces is $p = 85 - q^2$, and suppose that their marginal cost is equal to their average cost and that value is 10. What is the profit maximizing level of output? What is the profit for the monopolist? Use a graph to help show your results.
